RESILIENT BEDDING OF BUILDINGS

VIBRATION ISOLATION OF BUILDINGS

Regupol®

Regufoam®

Regupol Australia
Vibration Isolation of Building Foundations

Various factors may subject buildings to shock which continues in their structure and is perceived by the people living in them as noticeable vibrations or secondary airborne noise. Specifically in areas with a dense infrastructure, these are typically vibration emissions from above- or underground railway lines and from industrial plants.

Especially the high prices of land in conurbations also make locations next to railway lines attractive if the buildings there are sufficiently isolated against the attendant vibrations. The price advantage of acquiring land that is exposed to vibrations of this kind far exceeds the additional expenditures for the resilient bedding of buildings. The materials made of Regupol® and Regufoam® have been developed to isolate vibrations. Numerous building foundations have already been successfully isolated against vibration impact with Regupol® and Regufoam®.

With Regupol® and Regufoam®, Regupol offers a total of 20 different materials.

Vibration remeasurements in already completed projects have shown that vibration isolation with these materials was sometimes able to achieve better results than the required minimum value determined in the forecast.

The material Regupol® is composed of rubber fibres, rubber granulates (SBR, NBR) and polyurethanes, and Regufoam® is a mixed-cell polyurethane foam.

All the physical properties of the vibration-isolating products of Regupol which the expert consultants require are sufficiently documented. Thanks to their different load ranges, various types of material can be used for different areas bearing different loads. Consequently, even demanding isolation jobs can be mastered.

The vibration isolation of buildings that is achieved with Regupol® and Regufoam® remains at a constantly high level for the long term. It has been possible to document the isolating effect of structures through control measurements after their completion and after ten years of use.

In cooperation with the expert consultants, Regupol has also developed specifically designed types or modifications of material for particularly demanding projects.

Regupol® and Regufoam® are suitable for all kinds of vibration isolation of buildings:

- Full-surface foundation bedding
- Strip foundation bedding
- Pointed foundation bedding
- Vertical lateral vibration isolation
- Decoupling underneath the basement ceiling
- Vibration isolation of individual parts of buildings
- Room-in-room constructions
- Slotted walls in the transmission area between energy source and building

The Benefits

- Isolation effect can be adjusted to the specific requirements
- Choice of two different product lines for the most economical and technically best solution possible
- Precisely definable tuning frequency thanks to individual material thicknesses

Regupol Australia

Made in Germany
- best quality
- fair pay
- secure jobs
- high environmental standards
The protection of buildings against vibrations can be achieved through different measures:

1. Vibration-reducing measures at the place of the emission, e.g. a mass-spring system in a railway track.

2. Interruption of the transmission of the vibration in the transmission area, e.g. through a below-ground slotted wall or by shielding the basement walls.

3. Shock and structure-borne sound decoupling at the place of immission, underneath the building foundations and at the exterior side of the basement walls at the earliest. This is the measure most commonly used.

Most decoupling measures are taken at the building foundations and are called resilient bedding of buildings. Railway tracks are one of the most frequent causes of emission. Therefore the majority of the measures apply to resilient bedding of buildings for interfering frequencies between 25 and 100 Hz. Vibrations in this frequency range are critical, as they can lead to building component resonances and thus to secondary sound effects.

Consequently, the resilient bedding of buildings is intended to reduce the transmission of vibrations in the structure of the building with the help of the isolating material and by taking complex impact factors into account. Lowering the level to between 10 to 25 dB, depending on the frequency, is no problem at all with Regupol® and Regufoam®.

Tasks

The vibrations which are caused by the source of the shock may spread throughout the building structure: they are perceived as noticeable vibrations, they can spread as secondary airborne sound, and when the worst comes to the worst, they can damage the building structure. What is more, the function of machines and measuring equipment in the building may be impaired.

The objectives of the vibration isolation of buildings are:

- health protection
- the protection of the building fabric
- the protection of the technical equipment inside the building

Shock is the common term for mechanical vibrations of solid bodies with a potentially damaging or disturbing effect.

Structure-borne sound refers to vibrations which, contrary to airborne sound, continue through a solid medium. Vibrations in liquids are called fluid-borne sound.

The transmission path of vibrations or of shock may include a change of media.
Types of Vibration Isolation of Buildings

The decision of which measures to take always depends on various impact factors and must be taken based on the individual case.

The vibrations to be expected at the place of immission (the building) depend on the composition of the frequency of the emission source, on the transmission via the specific ground, the coupling of the building and the continuation of the vibrations within the building structure.

Transmission Mechanism

Emission
- Type of excitation (railway traffic, industry, etc.)
- Level of excitation
- Composition of the frequency components

Transmission
- Spreading on the ground
- Coupling of the building
- Elastic decoupling
- Impact of the ceilings (building component resonances)

Immission
- Vibrations to be expected in the building (e.g. on finished floor)

Impact factors for the transmission of vibrations.

As a rule, the existing situation should be assessed by taking vibration measurements. With the help of complex, computer-assisted calculation models the expert consultants can then come up with a forecast for the property and define the “target situation” of the resilient measure. The resulting requirements of support frequency and isolation effect make it possible to develop the optimum solution from an economical and technical point of view when Regupol® and Regufoam® are used.

Elastic decoupling is only effective if certain specifications are adhered to during the installation. Special care must especially be taken to make sure that there are no direct connections (structure-borne sound bridges) between the property to be protected and its surroundings.

The decision of where the resilient measure is to be applied at the building depends on the properties of the foundation. We distinguish between full-surface decoupling underneath the base plate, strip decoupling under strip foundations, the rising walls or point decoupling. When exterior building components touch the ground above the decoupling level, it is necessary also to decouple them vertically from the ground.

Vertical Decoupling

In some cases it suffices to install a vertical partition at the exterior structural components in order to reduce vibrations. Vertical partitions are often installed between existing and to-be-constructed buildings.

In these applications there are diverse requirements of the elastomer. The more dynamically soft the material, the better the reduction of the vibration. However, it still has to be able to bear the loads that occur. These loads, which may be the result of earth or concreting pressure, may be up to 120 kN/m² and in exceptional cases even considerably higher.

Generally a plate-shaped, soft elastomer from the Regupol® group is used for this type of application. Even though they have a constant load-bearing capacity of up to 120 kN/m², Regupol® elastomers still have very low dynamic rigidity. Moreover, the material is insensitive to moisture and very quick to install thanks to the installation aids.

The material is available in plates of 1,000 x 500 x 50 mm as standard to ensure good handling. Depending on the requirements for the vertical isolation, the material can also be installed in double layers with 100 mm thickness. Special thicknesses (e.g. 25 mm) are available upon request.

The vertical isolation can be glued onto the partition wall. To this end the construction site must offer the usual gluing conditions such as a dry and dust-free surface.

Alternatively, the material can be nailed or plugged onto the wall with mounting aids, regardless of the weather conditions.

Prior to backfilling the site, the elastomer should be protected against sediments and sharp rocks by covering it with a geotextile.
Full-Surface Decoupling

In full-surface decoupling, the entire base plate is separated elastically from the building ground. The elastomer is either applied on a thicker foundation course or on a specially dimensioned supporting plate.

To achieve optimum efficacy, the foundation should be as rigid as possible. Since it is a full-surface installation, the isolation can be performed quickly and easily, and the risk of acoustic bridges is very low, too.

The building loads are distributed over a large area of the subfloor. The degree of rigidity of the elastomers is selected by taking the different compression ranges into account. As a result, fairly even deflection of the entire base plate can be achieved.

The base plate and the adjoining structural components should also be as rigid as possible so as to avoid vibration of the structural components and dynamically activating large masses of material.

Finally, the elastomer must be covered with PE foil for protection against concrete slurries.

Full-surface decoupling of a building foundation with Regupol®/Regufoam® vibration damping material: 1 natural surface • 2 impedance plate • 3 Regupol®/Regufoam® vibration isolation • 4 foundation plate • 5 basement wall • 6 floor slab
Strip Decoupling

Linear decoupling is a vibration isolation option for buildings with strip foundations. The width of the foundation should be such that the elastomers are used optimally by the load-bearing area to make sure that the best isolation effect can be achieved.

An alternative option is strip decoupling on the rising walls underneath the basement ceiling. With this method, it is also possible to do without vertical isolation of the exterior structural components towards the ground.

The adjoining structural parts, such as ceilings on top of the structural part, must be sufficiently rigid to avoid vibrations of the structure. Installation can be done either with in situ concrete or using prefabricated parts.

To prevent the penetration of concrete slurries into the elastomer, the latter should be protected by a PE foil with a thickness of at least 0.2 mm.

Strip decoupling of a building foundation with Regupol®/Regufoam® vibration damping material: 1 natural surface • 2 impedance plate • 3 Regupol®/Regufoam® vibration isolation • 4 foundation plate • 5 basement wall • 6 floor slab
Point Decoupling

Because of the high point loads in foundations with poles and supports, elastomers with a high load-bearing capacity are typically used for vibration decoupling. The elastomers should already be included in the plan at an early stage to make sure that the vibration isolation can increase the security of the entire structure.

The pile cap structure can be optimised by keeping the pressure on the elastomer constant by varying the measurements. The result is an even deformation and isolation behaviour of the entire foundation construction and the elastomers.

The foundation structure should be rigid as well so as to activate adjoining parts of the overall structure as dynamic masses and to reduce structural vibrations.

The Clichy (France) Music School as a Real-Life Example

Decoupling of the building foundation of the Clichy Music School with Regupol® vibration damping material.

Regufoam® – Mixed-Cell Polyurethane Elastomers

Material Composition

Regufoam® elastomers consist of a mixed-cell polyurethane foam. Similar to the various Regupol® types, Regufoam® isolation materials have been precisely designed for different load ranges. Various standard thicknesses of 12.5 mm, 25 mm, 37 mm and 50 mm cover a wide spectrum of support frequencies up to 8 Hz.

The successful use of polyurethanes in vibration isolation over the course of many years offers expert consultants a conventional solution and a valuable alternative to Regupol® elastomers.

Moreover, the BSW test lab offers the option of developing project- and application-specific elastomers with special properties. Regufoam® elastomers and their specific load ranges can be distinguished from one another using colour codes (green, yellow, purple, blue, black, grey, beige, rose, turquoise, red, brown, orange).

Possible Uses

Due to their different dynamic rigidities and admissible load ranges, building and machine foundations can be placed elastically on strips or delicate point supports. Due to the low support frequencies, this type of support is technically efficient, but more difficult to plan and execute.

The majority of isolation jobs are performed on full-surface Regufoam® elastomers with lower rigidity, because this is more feasible and less error-prone.

The technical details, clearly arranged and determined as well as tested, provide a full overview of the load range of the Regufoam® elastomers and their non-linear material properties. They allow expert consultants to select and properly size the elastomer type that suits the situation at hand and meets its respective requirements.

Regufoam® elastomers are moisture- and rot-resistant. They are also ozone-resistant, but the colours may fade over time due to UV radiation. Because of their mixed-cell structure, especially types with lower dynamic rigidity can absorb water. These must be protected against water uptake.

Effectiveness of the Regufoam® Elastomers

Regufoam® elastomers can be specifically set for support frequencies between 20 Hz and 8 Hz in a broad load range from 0.011 N/mm² to 2.50 N/mm². Expert consultants in particular benefit from this large degree of flexibility.

The use of polyurethanes in vibration isolation over the course of many years offers expert consultants a conventional solution and valuable alternative. The admissible continuous load limits must be kept, as overload on the elastomers may lead to creep as well as rigidification of the material.

Regufoam® elastomers are produced and shipped in rolls. They can be cut to size with a standard utility knife right at the construction site. The professional company at the construction site is thus ensured that the installation is going to be simple, quick and, above all, cost-efficient.
Regupol® vibration is a rubber-polyurethane-composite for vibration isolation. It is available in 8 different qualities.

Technical services and offers based on these are subject to our General Terms and Conditions of sale, a copy of which can be found on our website www.berleburger.com. Special attention should be paid to paragraphs 4 and 5. In so far, please be advised as follows: Our expertise is the development and manufacturing of products. With our recommendation we can only assist you in selecting a product that is suitable for your demand. However, we cannot act as your architect or consulting expert. This would only be possible subject to a separately concluded service contract that we would have to bill you for. Such contracts are not part of our scope of supply and services. Hence, our recommendation does not lay claim for its correctness. Guarantees do only apply to the technical properties of the material supplied. Comment on tolerances: All technical values correspond to our current state of knowledge and are to be understood as reference values only. These values can be subject to considerable variations due to production and/or material reasons as well as due to outside influences (temperature, humidity etc.). Thus special agreements on material parameters might be necessary on a case-by-case basis.
Regupol® Elastomer Mats

Material Composition

Regupol® elastomers are composed of SBR and NBR rubber elements. For their production, rubber granulates, rubber fibres and rubber crumbs are combined with one another, processed and elasticised with various polyurethanes using a special manufacturing method.

Eight different Regupol® elastomers are available for the daily requirements. They can be used in a very wide load range if required.

The Regupol® elastomers offer a solution that is technically sufficient as well as the most economical one available for most vibration-technology-related jobs.

Moreover, the BSW test lab offers the option of developing special, project- and application-specific types which can be given desired elastomer properties.

Regupol® elastomers can be distinguished from one another based on their individual load ranges and, accordingly, their dynamic rigidities.

Possible Uses

Regupol® elastomers are suitable for all different kinds of vibration isolation.

Due to higher dynamic rigidities and the admissible load ranges of some elastomer types, buildings and machine foundations can either be bedded elastically on strips or on delicate point supports. Due to the low support frequencies, this type of support is technically efficient, but more difficult to plan and execute. The majority of isolation jobs are performed on full-surface Regupol® elastomers with lower rigidity, because this is more feasible and less error-prone.

The technical details provide a full overview of the load range of the Regupol® elastomers and their non-linear material properties. They allow expert consultants to select and properly size the elastomer type that suits the situation at hand and meets its respective requirements.

Additional benefits of Regupol® elastomers are their excellent moisture resistance, their rot-proof properties, their ozone resistance and their permanent elasticity even after frost-thaw cycles.

The use of Regupol® is therefore admissible not only inside but also outside of buildings. The only exception here is Regupol® vibration 200. Because of its rigidity and its cellular structure this material has to be protected against water uptake.
The technical information given in the documents are guideline values. They are liable to manufacturing tolerances, which may vary depending on the type of underlying properties. The currently valid versions of this information are provided on our internet pages and in the PDF versions of this catalogue. The PDF versions are available to download from our website.
